The difference is that the low fee always allows for scaling of the reference transaction, and is the lowest fee that allows for scaling of the reference transaction. Before the lowest fee that allowed for scaling of the reference transaction was the normal fee which was higher than the minimum required for scaling above 300000 bytes.

# 3) Reference transaction, $T_R$ , Minimum penalty free zone, $Z_M$ , and Median calculation after a fork.

Note: I am not recommending that we reduce  $T_R$  from the current 3000 bytes until, at least, we finalize the transaction size for Triptych or another replacement for CLSAG, if Triptych is not used. This is to reduce the impact on fees overall. For example: A reduction in fees followed by an increase in fees or the need to increase  $Z_M$  more than would be necessary.

 $T_{2C}$  = Weight in bytes of a 2 input and 2 output transaction for the current Monero version rounded up to the nearest 100 bytes.  $T_{2P}$  = Weight in bytes of a 2 input and 2 output transaction for the previous Monero version rounded up to the nearest 100 bytes. If a future Monero fork does not permit a 2 input and 2 output transaction then the permitted transaction in both versions with the lowest number of inputs and outputs greater than or equal to 2 is used instead.

## Calculation of T<sub>R</sub>

 $\begin{array}{l} T_{\text{RP}} = T_{\text{R}} \text{ of previous Monero version} \\ T_{\text{RC}} \text{ of current Monero version is set as follows: } T_{\text{RC}} \geq T_{\text{2C}} \\ \text{Recommendation (See: Note) } T_{\text{RC}} = \max(T_{\text{2C}}, T_{\text{RP}}) \\ T_{\text{R}} = T_{\text{RC}} (= 3000 \text{ bytes for BP+ fork if ring size} < 26) \end{array}$ 

## Calculation of Z<sub>M</sub>

$$\begin{split} & Z_{\text{MP}} = Z_{\text{M}} \text{ of previous Monero version} \\ & Z_{\text{MC}} = max(Z_{\text{MP}}, Z_{\text{MP}} T_{\text{RC}} / T_{\text{RP}}) \\ & Z_{\text{M}} = Z_{\text{MC}} \ (= 300000 \text{ bytes if } T_{\text{R}} = 3000 \text{ bytes}) \end{split}$$

Calculation of  $M_L$ ,  $M_S$ ,  $M_{LW}$  and  $M_{SW}$  where  $M_L > Z_{M_i}$  or would be under (ii), and where blocks from a previous Monero version are included in a calculation after the fork.

(i) For  $T_{2C} \leq T_{2P}$ 

 $M_{\text{L}},\,M_{\text{S}},\,M_{\text{LW}}$  and  $M_{\text{SW}}$  are calculated in the usual way with no reduction is size applied to the pre fork blocks

(ii) For  $T_{2C} > T_{2P}$ 

When blocks of previous Monero are included in a calculation after the fork version  $M_B$  for the pre fork blocks is replaced by  $M_{BC}$ , where  $M_{BC} = M_B T_{2C}/T_{2P}$ . The current value of  $Z_M$  is used, and the starting median for  $M_L$  and  $M_{LW}$  may also need to be adjusted. This needs to be looked at for each specific fork case. There may be a one time increase in  $M_L$ ,  $M_S$ ,  $M_{LW}$  or  $M_{SW}$  at the fork.
